DNA and RNA molecules are polymers. DNA is double stranded, whereas RNA is single stranded. The nucleotides of DNA can pair together by base pairing, creating a strand that is complementary to its pair; Various types of RNA exist which have roles in protein synthesis as well as regulation of cellular programmes by fine-tuning gene expression.

In biology, epigenetics is the study of heritable phenotype changes that do not involve alterations in the DNA sequence. The Greek prefix epi- ("over, outside of, around") in epigenetics implies features that are "on top of" or "in addition to" the traditional genetic basis for inheritance. Epigenetics most often involves changes that affect gene activity and expression, but the term ...

DNA contains the base thymine, whereas RNA contains uracil instead. DNA contains the pentose sugar deoxyribose, whereas RNA contains the pentose sugar ribose. Differences Between the Polymers. DNA is much larger because it contains approximately 23,000 genes (the entire genome), whereas RNA is much shorter because it is only the length of one gene. DNA is double stranded, whereas RNA is single stranded. RNA is made from a DNA template.
